		DEGREES OF LATITUDE.												

TABLE XLIV.

Mean Right Ascensions and Declinations of 226 of the principal Fixed Stars, adapted to the beginning of the year 1824.

S, signifies south declination; all the rest are north.

Names of the stars.	Magnitude.	Right ascension	Annual variation.	Declination	Annual variation.	Bearing and true spherical distance of an adjacent brilliant star; very useful in deducing the Latitude from the Altitudes of two fixed stars.	Annual variation in distance.

The Mean Right Ascensions and Declinations of the principal Fixed Stars, continued.

S. signifies south declination ; all the rest are north.

Number.	Names of the stars.	Magnitude.	Right ascension.	Annual variation.	Declination.	Annual variation.	Bearing and true spherical distance of an adjacent brilliant star ; very useful in deducing the Latitude from the Altitudes of two fixed stars.	Annual variation in distance.

Declination, of the same name with the Latitude.													

Altitude of a Celestial object, (when its centre is in the prime Vertical,) most proper for determining the Apparent Time with the greatest accuracy.

Declination of the object, of the same name as the Latitude.

Declination of the object, of the same name as the Latitude.

Amplitudes of a celestial object, reckoned from the true East, or West Point of the Horizon.

Declination of the object of the same name with the Latitude.

Note.—When the object either comes to, or within one degree of the zenith, the angle of meeting made by the latitude and the declination (both of the same name) will fall within the double lines which run obliquely through the body of this Table, and through the upper left hand corner of Table LII.; in this case, since the interval between the time of observation and noon or meridional passage, must not exceed one minute, the corresponding number will, therefore, be the correction of altitude direct, independently of any logarithmic calculation whatever.

FOR COMPUTING THE MERIDIONAL ALTITUDE OF A CELESTIAL OBJECT.

		Declination of the object of a different name with the Latitude.														Latitude

FORM OF A TRANSIT TABLE.

SINCE the method of determining the latitude by the meridional altitudes of the fixed stars and planets is now become generally prevalent in most sea-going ships, and since it is essentially necessary, and conducive to the accuracy of the result, to be duly apprized of the mean times of transit; the navigator should, therefore, have a small book made, containing all the stars that will transit, or pass over the meridian of his ship during night:—this book might be called a Transit Table (or any other appropriate epithet), and should be kept in the binnacle, or some other convenient place, where it concerned could have easy and constant access to it: the book should be ruled, and the columns filled agreeably to the following form:—

Names, or characters of the Stars.	Declination.	Days of the Month.—suppose January 1824.—								
		1	2	3	4	5	6	7	8	9
		Mean Time of Transit.

Mars	0 51. 0 N	17.31. 0	17.28. 0	17.25. 0	17.22. 0	17.19. 0	17.16. 0	17.12. 0	17. 9. 0	17. 6. 0

By extending the above Transit Table to the star α Lupi it will be seen that 137 fixed stars, exclusive of the three planets, will pass the meridian on the 1st night of the given month; by all of which the latitude may be very accurately determined, provided the night be sufficiently clear for observing the meridional altitudes.

Note.—The mean times of transit in the first column are to be computed by the following rule; viz:

From the right ascension of the star (increased by 24 hours if necessary), subtract that of the sun at noon of the given day, and the remainder will be the approximate time of transit; to which if the longitude, in time, be applied by addition in west, or subtraction in east, and the sum, or difference, will be the Greenwich time.

With the Greenwich time, thus found, enter Table XLVI., and find the corresponding minutes and seconds; which being added to the approximate time of transit if the Greenwich time precedes the sun of the given day, or subtracted therefrom if it be past that noon, the sum, or difference, will be the correct mean time of transit.

The transits in the 1st column, being thus carefully determined, may be reduced to several subsequent nights by continually subtracting therefrom the daily increase or variation of the mean sun's right ascension.

Remark.—All the stars whose declinations are greater than the latitude, and of the same name, will never set, or go below the horizon, in that latitude: those are called circumpolar stars, and will always pass the meridian below the Pole in 12 hours, diminished by half the daily variation of the mean sun's right ascension, after the times of transit found as above. (See Problem VIII., page 348.)

The least altitude of a circumpolar star indicates its being on the meridian below the Pole, which altitude will be expressed by the difference between the star's polar distance and the latitude of the place of observation.

The Author has invented a *Universal Stellarium*, which answers the purpose of a *general Transit Table*; it shows the correct mean times that the fixed stars will transit, or come to the meridian in all parts of the world, without the trouble of calculation,

Table showing the true time at which the hour and minute hands of a well-regulated watch, or clock, should be in conjunction, and, also, in opposition, in every revolution.

Number of Conjunctions.	Time of Conjunction.				Number of Oppositions.	Time of Opposition.			
	Hours.	Minutes.	Seconds.	Decimals.		Hours.	Minutes.	Seconds.	Decimals.
1	1	5	27	. 273	1	1	38	10	. 909
2	2	10	54	. 545	2	2	43	38	. 182
3	3	16	21	. 818	3	3	49	5	. 455
4	4	21	49	. 091	4	4	54	32	. 727
5	5	27	16	. 364	5	6	0	0	. 000
6	6	32	43	. 636	6	7	5	27	. 273
7	7	38	10	. 909	7	8	10	54	. 545
8	8	43	38	. 182	8	9	16	21	. 818
9	9	49	5	. 455	9	10	21	49	. 091
10	10	54	32	. 727	10	11	27	16	. 364
11	12	0	0	. 0	11	12	32	43	. 636

Note.—The above Table was computed in the following manner, viz:—While the hour hand goes once and the dial-plate, the minute hand goes round it twelve times; hence the minute hand gains 11 complete rounds, over the hour hand, in every 12 hours: Therefore, as 11 hours, are to 12 hours; so is the next less hour to the true time of conjunction.—And, as 11 hours, are to 12 hours; so is the next less hour and its half, to the true time of the hands being in opposition.—Thus:—
To find the time that the hour and minute hands of a well-regulated watch, or clock, will be in conjunction, and also in opposition, between the hours of 1 and 2 o'clock.
As 11 hours : 12 hours :: 1 hour : 1^h. 5^m. 27^s. 273, which, therefore, is the true time of the hands being in conjunction.

And:

As 11 hours : 12 hours :: 1½ hour : 1^h. 38^m. 10^s. 909, which, therefore, is the true time of the hands being in opposition: and so on for the other conjunctions and oppositions.

CAPTAIN WILLIAM FITZWILLIAM OWEN'S

TABLE OF LATITUDES AND LONGITUDES.

THE following Table is an accurate copy of the several series of Latitudes and Longitudes established, astronomically and chronometrically, by WILLIAM FITZWILLIAM OWEN, Esq., Captain of his Majesty's ship *Eden* (late of the *Leven*), during his extensive survey of the coasts of Africa, Arabia, Madagascar, Brazil, &c. &c., between the years 1820 and 1826, inclusive: of which series Captain Owen has kindly allowed the publication in this work; and from that officer's general experience as a navigator, a practical astronomer, and an hydrographer, it is presumed that every degree of confidence may be placed in the positions of the places contained in this Table; particularly in such positions as have been determined under his own immediate observation, which have the *Leven*, or the *Leven* and *Barraconta* in the column of authorities.

Remark.—The Table in question has been corrected agreeably to the “Errata for the Tables of Latitudes and Longitudes compiled by Captain W. F. W. OWEN, R.N.”; which “Errata” the author of this Work had the honour of receiving from the Hydrographical Office, at the Admiralty, in the year 1829.

Note.—The Latitudes in this Table are inserted from Mr. Horsburgh's Directory, and the Longitudes are here marked, as observed on board the Leven; but as their determination was not at that time the particular object of her voyage, they do not perhaps merit the same degree of confidence as those in the other parts of the Table.

W. F. W. OWEN.

APPENDIX.

SHOWING the Method of finding the Ratio which the Circumference of a Circle bears to its Diameter; the Method of deducing the Natural Sines from the Circle, both numerically and geometrically; and, the Method of performing the Operation called "TETRAGONISM," or the *Squaring of the Circle*.

To find the Ratio which the Circumference of a Circle bears to its Diameter.

Since the ratio of a circle, as determined and handed down to us by the ancients, is generally taken for granted without any direct evidence; being thus more practically than theoretically understood; I shall therefore investigate the principles upon which it is founded, for the satisfaction of all persons who may be at all curious in such an interesting inquiry.

THEOREM.

If in any semi-circle, as ADEB, chord-lines be drawn from the extremities of two equal arcs, as AD and DE, to meet in the point B determined by the chord AB, which passes through the centre: then will the middle chord BD be a mean proportional between the sum of the extreme chords AB and BE multiplied by the radius CB:—that is $AB + BE \times CB = BD^2$.

DEMONSTRATION.

Produce BE indefinitely, take BD in the compasses and lay it off from D to F: join DF, and also CD.—Now, because the chord AD is equal to the chord DE, the angle ABD, or CBD, is therefore equal to the angle DBE or DBF; for it is evident that equal arcs must be subtended by equal angles. (Euclid, Book III., Prop. 27.) And because BC is equal to CD, and BD equal to DF by construction, the two triangles CBD, and DBF are isosceles; but the angles at the base of an isosceles triangle, or side opposite to the vertex, are equal (Euclid, Book I., Prop. 5): hence the angle CBD is equal to the angle CDB; and the angle DBF is equal to the angle DFB or = DFE; for all these angles being the subtenses of equal arcs, they are therefore mutually and respectively equal to each other. And since the angles at the base BD are equal to the angles at the base BF; the angle at the vertex BCD of the one is equal to the angle at the vertex BDF of the other: wherefore the two triangles CBD and DBF are isosceles, by Euclid, Book I., Prop. 6; and they are also equiangular and homologous. — Hence, per similar triangles, Euclid, Book VI., Prop. 4.,—

As $BC : BD :: BD : BF = BE + EF$:—hence, $BE + EF \times BC = BD^2$.

We have now to prove that the side EF is equal to the side AB.

Because the quadrilateral figure ADEB is inscribed in a semicircle, the opposite angles are equal to two right angles (Euclid, Book III., Prop. 22). And because the angle in the segment DEB, which is less than a semicircle, is obtuse; the opposite angle in the segment DAB, which is greater than a semicircle, is acute; and therefore the sum of the two angles is equal to two right angles. (Euclid, Book III., Prop. 31.)

Now, the exterior angle DEF of the quadrilateral figure ADEB is equal to the opposite interior angle DAB; for the sum of the adjacent angles DEF and DEB is equal to two right

angles (Euclid, Book I., Prop. 13); and we have just seen that the sum of the two opposite angles DEB and DAB is equal to two right angles: therefore, $DEF + DEB$ is evidently equal to $DEB + DAB$: from each of these equals take away the common angle DEB, and then the remaining angle DEF will be manifestly equal to the remaining angle DAB; for, if equals be taken from equals, the remainders are equal.

Now, since it has been demonstrated that the angle ABD is equal to the angle DFE; and that the angle DAB is equal to the angle DEF; and since the side AD, of the triangle ADB, is equal to the side DE of the triangle DEF; and, moreover, since the angles at the base AB are respectively equal to the angles at the base EF; therefore the remaining angle ADB of the one is equal to the remaining angle EDF of the other; and they are right angles, because ADB is an angle in a semicircle. (Euclid, Book III., Prop. 31.)

But when two sides and the contained angle of one triangle are respectively equal to two sides and the contained angle of another triangle, the remaining or third side of the one is equal to the remaining or third side of the other. (Euclid, Book I., Prop. 4.) Therefore, the side EF is equal to the side AB; consequently the two triangles ADB and EDF are identically equal in every respect.

Having thus demonstrated that the side EF is equal to the side AB, the above proportion, viz., as $BC : BD :: BD : BF (= BE + EF)$, becomes, as $BC : BD :: BD : 2BC + BE (= AB + BE = BE + EF)$. Then, by taking the rectangles of the extremes, it will be $2BC + BE \times BC = BD^2$; but since the radius BC is unity or 1, and that multiplying by 1 is useless; there the expression becomes $2BC + BE = BD^2$,—or $\sqrt{2BC + BE} = BD$, in which $2BC = AB = EF$. Wherefore, if the measure of the supplemental chord of any arc of a circle, whose radius is unity or 1, be increased by the number 2, or the value of the diameter, the square root of the sum will express the correct measure of the supplemental chord of half that arc. Thus, if AD be bisected, then $\sqrt{BD + 2} =$ the supplemental chord of the bisection adjacent to the diameter AB.

As the arcs AD and DEB make a semicircle, they are the supplements of one another, and therefore if the arc AD be taken as $\frac{1}{2}, \frac{1}{3}, \frac{1}{4}$ &c. of the circumference, the line BD becomes the supplemental chord of that arc.

Now, from the above theorem we can readily find the true ratio which the circumference of a circle bears to its diameter.

Let the arc AD, in the annexed diagram, be taken equal to the radius unity or 1, and it will be the side of a hexagon inscribed in a circle. (Euclid, Book IV., Prop. 15.) Draw BD and it will be the supplemental chord of AD. Let the side of the hexagon AD be bisected successively, as Ad^1, Ad^2, Ad^3 &c., as far as convenient; in this instance we will extend it to the twelfth bisection, or Ad^{12} , which will reduce the circle to a regular polygon, consisting of 24576 sides: that is, it will express the side of a polygon equal to the 24576th part of the circumference of a circle whose radius is unity or 1. Join Bd^1, Bd^2, Bd^3 , &c., and they will be the supplemental chords of the arcs of those bisections.

Now, since the radius AC or BC is unity, consequently the diameter AB is 2; and since AD is equal to the radius, and that the triangle ADB is rectangular (Euclid, Book III., Prop. 31),—Therefore, in the right-angled triangle ADB, the hypotenuse AB, and the leg AD are given, to find the leg BD: hence, by Euclid, Book I., Prop. 47,— $\sqrt{AB^2 - AD^2} = BD =$ the supplemental chord of the arc AD of the one-sixth part of the circumference. Then, working agreeably to the theorem, it will be $\sqrt{2 + BD} = Bd^1$; $\sqrt{2 + Bd^1} = Bd^2$; $\sqrt{2 + Bd^2} = Bd^3$, &c. &c. Thus by numbers.

Since $AB = 2$, and $AD = 1$; therefore the square of $AB = 4$, and that of $AD = 1$; then, $4 - 1 = 3$; and $\sqrt{3} = BD = 1.732050807568877293527446341506$, &c. &c. = the measure of the supplemental chord of AD. To this add 2, and the sum will be

3.732050807568877293527446341506, the root of which is $Bd^1 = 1.931851652578136$, &c. &c.; to this add 2, and the sum will be 3.931851652578136, &c. &c., the root of which is $Bd^2 = 1.982889722747620$, &c. &c.; to this add 2, and the sum will be 3.982889722747620, &c. &c., the root of which is $Bd^3 = 1.995717846477207$, &c. &c.; proceeding after this manner, the twelfth extraction will give $Bd^{12} = 1.999999346361928443818721918099819283031$; increase this by 2, and the sum will be the square of the supplemental chord Ad^{12} . Now, the square of AB — the square of Bd^{12} = the square of the chord Ad^{12} . Hence, $AB^2 = 4.0000$ &c. &c.

$$\text{And } Bd^{12} + 3 = 3.999999346361928443818721918099819288031$$

Difference of the squares = square of $Ad^{12} = 0.000000653638071556181278081900180711969$, the root of which is 0.00025566346464760687; which therefore is the correct length of the chord Ad^{12} , or the measure of the side of the inscribed polygon of 24576 sides. Hence, $0.00025566346464760687 \times 24576 = 6.28318530717958643712$ is the perimeter of a regular polygon of 24576 sides inscribed in a circle whose radius is unity or 1; which perimeter must approximate so very closely to the circumference of its circumscribed circle, that the one may be substituted for the other without producing any sensible difference.

Now, to show the very close approximation of the circumference of the circle and the perimeter of its inscribed regular polygon of 24576 sides.—Let AB , in the annexed diagram, represent one of the sides of that polygon = 0.00025566346464760687, and let EF represent the side of another regular and similar polygon described about the circle. Bisect AB in D , and draw the perpendicular CDG . Then, as AD is the half of AB ; it is therefore equal to 0.000127831732323803435. Now, in the right-angled triangle ADC , the hypotenuse AC and the leg AD are given, to find the leg CD . Hence,

The square of AC or 1 = 1.0000 &c. &c.

The square of AD = 0.00000016340951788904531952047504517799225

Difference = $CD^2 = 0.99999983659048211095468047952495482200775$, the root of which is 0.99999991829524072169 = the measure of CD . Then, because of the parallels AB and EF (Euclid, Book VI., Prop. 2), it will be as $CD : AB :: CG (= CA) : EF$. Thus, as 0.99999991829524072169 : 0.00025566346464760687 :: 1 : 0.00025566346673649907 = EF , or the measure of the side of the circumscribed polygon of 24576 equal sides. Hence, $0.00025566346673649907 \times 24576 = 6.28318535851620114432$, is the perimeter of the circumscribed polygon. Now, the circumference of the circle being greater than the perimeter of the inscribed polygon, but less than that of the circumscribed polygon, it must consequently be greater than 6.28318530717958643712

And less than 6.28318535851620114432

$$\text{Sum of Perimeters} = 12.56637066569578758144$$

Half sum . . . = 6.2831853284789379072; which is equal to the circumference of a circle whose radius is unity or 1; and which is strictly correct to the *ten-millionth decimal place*. And since the circumference of the circle is greater than the perimeter of the inscribed polygon, and less than that of the circumscribed polygon; it must therefore lie evenly betwixt those perimeters; and since the perimeters exactly correspond with each other as far as the *ten-millionth decimal place*; therefore the circumference of the circle which lies evenly between them must evidently be equal to, and actually correspond with, them to the *ten-millionth decimal place*; which is as great a coincidence as the most rigid species of calculation requires.

Now, since circles are to each other as their diameters; therefore, 6.2831853284789379072

$+ 2 = 3.14159266642394689536$, is the correct circumference of a circle whose diameter is 1.—And since this coincides with the perimeters of its inscribed and circumscribed polygons, to the ten-millionth decimal place; therefore, 3.14159266 is the true *ratio of the circumference of a circle to diameter unity or 1*.

Having thus found the ratio of the circumference of a circle to diameter unity, we have only to determine a few of the natural sines; and if these agree with the natural sines deduced geometrically from the circle;—then, we shall have a very satisfactory and conclusive proof that the ratio of the circumference of a circle to its diameter is as above stated.

Since the diameter of the trigonometrical circle is 2; therefore, $3.14159266 \times 2 = 6.28318532$ is the circumference of the circle used in the trigonometrical canon. And since the circumference of all circles contains 360 degrees, or 21600 minutes; therefore, $6.28318532 \div 21600 = 0.0002908882$ is the chord of the arc of 1 minute; but since the chord of so small an arc as one minute of a degree, and which is adapted to a radius so exceedingly minute as to be only the ten thousand millionth part of unity, or 1 line (this is the *true radius of the trigonometrical canon*), is physically equal to its sine; therefore, the natural sine of 1 minute is 0.0002908882. Now, having thus found the value of one minute, the natural sines of every minute in the quadrant may be readily obtained by the following formula, viz. :—

From twice the sine of the mean arc betwixt any two equidistant extremes subtract the sine of the given extreme, and the remainder will be the sine of the other extreme,* as thus :—

To find the sine of 2 minutes.

Sine of $1' = .0002908882 \times 2 = .0005817764$
 Subtract the sine of $0' = .0000000000$

The sine of 2 minutes = .0005817764

To find the sine of 4 minutes.

Sine of $3' = .0008726646 \times 2 = .0017453292$
 Subtract the sine of $2' = .0005817764$

The sine of 4 minutes = .0011635528

To find the sine of 3 minutes.

Sine of $2' = .0005817764 \times 2 = .0011635528$
 Subtract the sine of $1' = .0002908882$

The sine of 3 minutes = .0008726646

To find the sine of 5 minutes.

Sine of $4' = .0011635528 \times 2 = .0023271056$
 Subtract the sine of $3' = .0008726646$

The sine of 5 minutes = .0014544410

Proceeding in this manner, the natural sine of 1 degree will be found to be .0174524; the natural sine of 15 degrees, .2588190; the natural sine of 30 degrees, .5000000; that of 45 degrees, .7071068; that of 60 degrees, .8660254; that of 75 degrees, .9659258; and that of 90 degrees, 1.0000000.

Now, having found the sines of those arcs, let us see whether they coincide with the sines of similar arcs, which flow *naturally* from the geometrical properties of the circle; and, if so, it will be a direct mathematical proof that the preceding ratio of the circumference of a circle to diameter unity has been truly determined.

Let the circumference of the circle in the following diagram be described with the radius of 10000, taken from any scale of equal parts; and let it be graduated to every tenth degree.—From the points 80, 70, 60, &c. in the semi-circle A B S, draw the vertical parallels 80, 70, 60, &c., meeting the semi-diameter C B in the points 8, 7, 6, &c.—And from the points 10, 20, 30, &c. in the semi-circle R A B, draw the horizontal parallels 10, 20, 30, &c., meeting the radius C A in the points 8, 7, 6, &c.; then, the former will represent the *natural sines*, and the latter the *natural co-sines* of those parallels.

The sines and co-sines thus determined, are denominated *natural*, because they flow naturally from the circle without the intervention of art.

If the radius C A (= C B) of 10000 equal parts be taken from any good-sized diagonal scale, the measure of the natural sines and co-sines, thus flowing from the circle, will be found to agree (as near as can be expected from projection) with the natural sines and co-sines given in the common Trigonometrical Tables.

Thus, in the quadrant A B, the extent from 30 to 3, or the sine of 30 degrees, is .5000; and from 30 to 6, the co-sine of 30 degrees is .8660. The extent from 45 to 1 = the sine of 45 degrees is .7071; that from 45 to 6, or the co-sine of 45 degrees, is also .7071. The extent

* See the last paragraph in page 54, Volume I.

FH = the sine of 30 degrees:—but Ru is equal to half the radius; therefore, FH , the sine of 30 degrees, is also equal to half the radius = RK .—Now, since the radius is expressed by unity, or 1.0000000, its half, $RK = Ru = FH$, is 0.5000000; which, therefore, is the correct measure of FH , or the natural sine of 30 degrees.

Having thus found the sine of 30 degrees, its co-sine may be readily determined; for, in the right angled triangle CHF , the hypothenuse CF , and the leg FH , are given; to find the leg CH = the co-sine of 30 degrees.* Hence,—

$$CF^2 \text{ or } 1.0000000^2 = 1.00000000000000$$

$$FH^2 \text{ or } .5000000^2 = .25000000000000$$

Difference of squares = 0.75000000000000 ; the root of which is $CH = 0.8660254$, which is the natural co-sine of 30 degrees; or the natural sine of 60 degrees: for, since the two triangles, CDK and CHF , are identically equal in every respect; therefore, the leg DK of the one, is equal to the leg CH of the other. Hence DK , or the sine of 60 degrees, is 0.8660254.

Again.—In the triangle RHF , the legs FH and RH are given; to find the hypothenuse RF . Thus,—

$$CR - CH = RH^2 (1 - .8660254) = .1339745^2 = 0.01794916665025$$

$$FH^2 \text{ or } 0.5000000^2 = .25000000000000$$

Sum of the squares = 0.26794916665025 ; the root of which is $RF = 0.5176381$; but since this is the chord of the arc, or the length of the side of the polygon RF ; therefore its half, or 0.2588190, is the measure of Gv , or the natural sine of 15 degrees; from which its co-sine, or the sine of 75 degrees, may be obtained; as thus:—

In the right angled triangle CvG , the hypothenuse CG and the leg vG are given; to find the leg Cv , the co-sine of 15 degrees, or the sine of 75 degrees. Hence,—

$$CG^2 = 1.0000000^2 = 1.00000000000000$$

$$Gv^2 = 0.2588190^2 = 0.06698727461000$$

Difference of squares = 0.93301272539000 ; the root of which is $Cv = 0.9659258$, which, therefore, is the natural co-sine of 15 degrees, or the natural sine of 75 degrees.

Now, on taking a comparative view of the values of the sines which flow from the circle, both naturally and geometrically, it will be found that they exactly correspond in every respect with the sines deduced from the ratio of the circumference of the circle to diameter unity; and, therefore, we have an unquestionable proof that the ratio deduced from a polygon of 24576 sides is 3.14159266, as particularly specified in page 665.

Remark.—If the bisection of the side of the hexagon AD , (see diagram, and the succeeding paragraph in page 663,) be continued to the *sixteenth place*, or AD^{16} ; it will reduce the circle to a regular polygon of 393216 sides; and since the more the sides are multiplied, the nearer will the polygon approach to a perfect circle; therefore, if the ratio of the circumference of the circle to its diameter be deduced from its inscribed and circumscribed polygons of 393216 sides, according to the principles laid down in pages 663 and 664, it will approximate to a still closer degree of exactness. In this case, the eighth decimal place will come out a 5 instead of a 6, thus making the ratio 3.14159265; and this is the ratio that is made use of in the miscellaneous problems at the end of the first Volume.

Now, from the ratio thus established we can easily deduce several useful recurring numbers, as in the following articles:—

1.—*To find the value of the Arc which is equal to the radius of the Circle.*

Since the circumferences of all circles are to each other as their diameters, and that the diameter of the circle used in the trigonometrical canon is 2; therefore, the circumference of that circle is 6.28318530:—hence its semi-circumference is 3.14159265, and its radius unity or 1. Now, since the semi-circumference of every circle is equal to 180 degrees; therefore, $180^\circ \div 3.14159265 = 57^\circ.2957795$ is the value of the arc, which is equal to the radius.—Or, let 180° be reduced to thirds; then $38880000'' \div 3.14159265 = 57^\circ.17'.44''.48''$, is the value of the arc in different denominations that is equal to the radius.

* See the first paragraph in page 54, vol. i.

2.—To find the length of the Arc of one degree of the Circle.

Since the measure of the semi-circle used in the trigonometrical canon is 3.14159265, and that this is equal to 180 degrees; therefore, $3.14159265 \div 180^\circ = 0.0174533$, is the length of the arc of one degree of the circle.

3.—To find the Area of a Circle whose diameter is unity or 1.

Every circle may be conceived to be a polygon of an infinite number of sides: for the sides of a polygon, inscribed in a circle, may be imagined to be so indefinitely multiplied, that each side shall be so far less than any assignable length, as to be reduced to a dimensionless point; and as a continued succession of those points, each being equally distant from the centre, forms a uniform curve; therefore, the perimeter of the polygon becomes such a *perfect curve* as to be identically equal to the circumference of its circumscribing circle; and, consequently, the perpendicular will become equal to the radius, and the area of the polygon equal to that of the circle.

In the annexed diagram, conceive a polygon of an indefinite number of sides to be inscribed in the circle ABFG, and that radii are drawn to all the angular points, dividing it into as many isosceles triangles as there are sides in the polygon;—let one of those triangles be expressed by the points FCH, and its perpendicular by the line CI.

Draw nI parallel to CF ; then, because the parallelogram $CnIF$ stands upon *half the base* of the triangle FCH, and between the same parallels, the area of the parallelogram is therefore equal to the area of the whole triangle.* Hence it is manifest, that half the side of the polygon FH, viz., the part FI, multiplied by the perpendicular CI, expresses the area of the triangle, and also the area of the parallelogram that stands upon *half* its base. Now, since the polygon consists of as many triangles as it has sides; therefore it is equal to a parallelogram that is comprehended under the rectangle of its perpendicular and a straight line that is equal to the length of *half* its perimeter. But, when the sides of a polygon are indefinitely multiplied, its perimeter is generated into the curve of its circumscribing circle; and therefore the area of a circle is equal to the area of a parallelogram whose shortest side is represented by the semidiameter, and its longest side by a straight line equal in length to the semi-circumference. Hence, every circle is equal to the rectangle which is comprehended under its semidiameter and the *half* of its circumference.

Now, since the circumference of a circle whose diameter is unity or 1, is 3.14159265, therefore, the product of half the circumference by half the diameter, viz., $1.570796325 \times 0.5 = 0.7853981625$, is the area, or superficies, of a circle whose diameter is unity or 1. And, because the areas of circles are to each other as the squares of their diameters (Euclid, Book XII, Proposition 2); therefore, if the square of the diameter of any circle be multiplied by 0.7853981625, the product will be its area.

4.—To find the Area of a Circle whose circumference is unity or 1.

Since the diameters of circles are to each other as their circumferences; and that the product of half the diameter by half the circumference expresses the area of the circle, as explained in Article 3; therefore, as 3.14159265 : 1 :: 1 to 0.318309, the diameter of the circle whose circumference is unity. Now, the half of this multiplied by the half of unity = $0.1591545 \times 0.5 = 0.079577$, is the area of a circle whose circumference is unity or 1. And because the areas of circles are to each other as the squares of their circumferences; therefore, if the square of the circumference of any circle be multiplied by 0.079577, the product will be the area of such circle.

* If a parallelogram and a triangle stand upon the same base and between the same parallels; the parallelogram shall be the double of the triangle. (Euclid, Book I., Proposition 41.)

6.—To find the side of a Tetragon or Square that is equal in area or superficies to a Circle whose diameter is unity or 1.

The area of a circle whose diameter is unity is 0.7853981625, as shown in Article 3.—Now, the square root of that area is 0.8862269; which, therefore, is the side of the square that is equal in area to a circle whose diameter is unity or 1. And, because the sides of tetragons, or squares, are as the diameters of their circumscribing circles; therefore, the product of the diameter of any circle by 0.8862269, will be the side of the square that is equal in area to such circle. Hence, if the radius of a circle be unity, or 1, its diameter will be 2; and, therefore, $0.8862269 \times 2 = 1.7724538$, is the side of a square that is equal in area to a circle whose radius is unity or 1. And because the sides of tetragons are as the diameters of their circumscribing circles; they are also as the radii or semidiameters of those circles. Hence, if the semidiameter of a given circle be multiplied by 1.7724538, the product will be the side of the square that is equal in area to the given circle.

7.—To find the Side of a Tetragon or Square inscribed in a Circle, the radius, or semidiameter, of which is unity or 1.

In the diagram, page 668, if the diameter of the circle be 2; its semidiameter, A C, or B C, will be unity, or 1. join A B, and it will represent the side of the inscribed tetragon, or square. Then (by Euclid, Book I., Prop. 47), $AC^2 + BC^2 = AB^2$. Hence, $1 \times 1 + 1 \times 1 = 2$; the square root of which is 1.41421356, and which, therefore, is the side of the tetragon inscribed in a circle whose radius or semidiameter is unity or 1.—Now, since the sides of tetragons, or squares, inscribed in circles are as the radii or semidiameters of those circles; therefore, if the semidiameter of any circle be multiplied by 1.41421356, the product will be the side of the tetragon inscribed in such circle:—hence, if the diameter of a circle be 1, its radius will be 0.5; then, $1.41421356 \times 0.5 = 0.70710678$, is the side of a tetragon, or square, inscribed in a circle whose diameter is 1.

8.—To find the Radius that will circumscribe a Square which is equal in area to a Circle whose semidiameter is unity or 1.

In the diagram page 668, let the radius or semidiameter of the circle be unity; then, the side of the inscribed square A B, found by Article 7, will be 1.41421356.—Now, the side of the square D E, which is equal in area to a circle whose radius is unity, or 1, is 1.7724538, as shown in Article 6:—hence, by similar triangles (Euclid, Book VI., Prop. 4).—As $AB : BC :: DE : EC$; that is, as $1.41421356 : 1 :: 1.7724538 : 1.2533142$; which, therefore, is the value of the side E C, or the radius that will circumscribe the tetragon, or square, which is equal in area to a circle whose semidiameter is unity, or 1. And since the radii of circles are as the sides of their inscribed tetragons, therefore, if the semidiameter of any given circle be multiplied by 1.2533142, the product will be the length of the radius that will circumscribe the square which is equal in area to such given circle.

Note.—As the radius B C is 1, and the radius E C 1.2533142; the difference = E B is therefore 0.2533142; and as this difference approximates to a fourth part of the radius B C = unity or 1; we thus see the reason why mechanics in squaring a circle always augment its semidiameter by the one-fourth part of its value.

9.—To Square the Circle.

The squaring of a circle, or *tetragonism*, is a subject that has frequently engaged the attention of the ablest mathematicians, ever since the days of the celebrated *Archimedes*, who was killed, at the storming of Syracuse, by the Romans, in the year 212 before the birth of Christ.

The reduction of a circle to a perfect geometrical square amounts to a mathematical impossibility; for, let the bisection of the side of the hexagon A D (see the diagram, page 663) be extended so far as to make the polygon consist of millions of sides; still, in extracting the square root of the last term, there will always be a remainder, or a visible fractional part of unity.—Hence, the ratio which the circumference of a circle bears to its diameter cannot be exactly determined; and therefore it is mathematically impossible to construct a square that shall be exactly equal in area to a given circle. However, although the perfect squaring of the circle is likely to remain for ever as a *desideratum*; yet, since the ratio of the circumference of the circle to its diameter is known to a very rigid degree of approximation; therefore a circle may be squared by means of that ratio to the utmost extent of any assignable point of exactness that can come within the range of geometrical and mechanical operations, as may be seen in the following example, viz.,—

To reduce a Circle whose diameter is 50 to a Geometrical Square.

Since the diameter is 50; therefore, by the last paragraph of Article 3, in page 668,— $0.7853981625 \times 50^2 = 1963.49540625$, is the area or superficies of the given circle. Now, agreeably to the latter part of Article 6, since the diameter of the given circle is 50, its radius or semidiameter is 25; then, $1.7724538 \times 25 = 44.311345$, is the side of the square that is equal in area to the given circle; and $44.311345 \times 44.311345 = 1963.49540625$ is the area of the square; being exactly equal to the area of the given circle, as shown above.—Again,

Since the semidiameter of the given circle is 25; therefore, computing in conformity with the latter part of Article 8,— $1.2533142 \times 25 = 31.332855$ is the radius that will circumscribe a square equal in area to the given circle. Having thus found the length of the radius, the circle may be *squared* by scale and compasses in the following manner, viz.—

With the semidiameter of the given circle = 25, in the compasses (taken from any scale of equal parts), describe the circle A B D E; through the centre C draw the diameter A B, and, at right angles thereto, the diameter D E; each of which produce at pleasure beyond the circumference.—

Take the computed radius 31.332855 in the compasses (from the same scale of equal parts); set one leg on the centre C, and note, by *points*, where the other leg falls on the produced diameters.

The connection of those points by right lines constitutes the square G H F I; which square is equal in area to the given circle:—for the four segments of the circle that are cut off by the four sides of the square, are equal in *value* to the four angles of the square that are cut off by the circumference of the circle.—Now, if one of the sides of this square be taken

in the compasses, and applied to the same scale of equal parts that the radii were taken from, it will be found to measure 44.31, &c. &c.; the square of which is 1963.4954, &c. And hence it is manifest, that as the area or superficies of the square G H F I, is numerically and physically equal to the area or superficies of the circle A B D E; the given circle is, therefore, reduced to a square that is both geometrically and mechanically equal to it in superficial content.

Remark.—If the circle be *squared* according to the mechanical mode, viz.—by *adding a fourth part to its semidiameter*, it will be productive of a considerable error; as thus,—the semidiameter of the given circle, as above, is 25; the one-fourth of which is 6.25; then $25 + 6.25 = 31.25$ is the mechanical radius for cutting the *produced diameters*.—Now, the side of the square corresponding to this radius (Article 7) is 44.19417375;—the square of this is only 1953.1248, &c.; which is 10.3706, &c., *less* than the area of the circle; and thus it is evident that the mechanical mode of *squaring the circle* is not correct; for the area of the square constructed agreeably to that mode will be always *less* than the area of the circle.

THE END.
